

malloc + free - how do they work?

They are C code

Key idea: on each malloc or free, store metadata about allocations  
Metadata is stored on the heap.

Malloc will create "blocks" on the heap.

Each block will have a special first 8 bytes called "header"

Header stores (a) the size of the block (b) if block is free or "busy" allocated

↑  
pointer returned from malloc

How to represent size+free in 8 bytes?

Invariant: all blocks start on a 8 byte boundary (all sizes are  $8n$ )  
so all sizes end in 000

Size is 64-bit unsigned number

Free/busy is the  $LSB=1 \Rightarrow$  busy  $LSB=0 \Rightarrow$  free

busy blocks

17		
----	--	--

malloc(16)

25			
----	--	--	--

free blocks

16		
----	--	--

24			
----	--	--	--

malloc(20)

- round up to 24
  - then write header 25
- (side note: realloc(24) ought to be in-place)

Heap size 400 bytes

Initial heap:

how many free  
bytes?

$a = \text{malloc}(40)$

$b = \text{malloc}(10)$

start at beginning  
of heap + search  
for free block
